# NUMERICAL INVESTIGATION OF NATURAL CONVECTION IN A VERTICAL ANNULUS ENCLOSURE 

Ass. Prof. Manal H. AL-Hafidh<br>University of Baghdad<br>Mechanical Eng. Dept

Safa Bontok Raheem<br>University of Baghdad<br>Mechanical Eng. Dept

#### Abstract

A numerical technique is developed to predict both the transient and steady axisymmetric two-dimensional natural convection heat transfer for water as the working fluid in a vertical annulus enclosure of a fixed radius ratio (2) aspect ratio (1) and Rayleigh number ranging within ( $10^{3} \leq \mathrm{Ra}_{\mathrm{d}} \leq 10^{6}$ ) for a fixed Prandtl number $(\operatorname{Pr}=7)$. Finite difference analogs of the Navier - Stokes and thermal energy equations are solved in the stream function - vorticity frame work. The results obtained are presented graphically in the form of streamline, vorticity and isotherm contour plots. A correlation has been set up to give the average Nusselt number variation with $\mathrm{Ra}_{\mathrm{d}}$ and for which the results are found to be in good agreement with previously published experimental data.

Numerical Investigation Of Natural Convection In A Vertical Annulus Enclosure

## INTRODUCTION

The annulus represents a common geometry employed in a variety of heat transfer systems ranging from simple heat exchangers to the most complicated nuclear reactors. In spite of the importance of convection heat transfer in vertical annular enclosures in many practical applications, very few basic studies have so far been conducted for this system. Many finite difference solutions of free convection problems of long horizontal, rectangular and cylindrical enclosures subject to lateral heating are found in the works of (Boyd, 1983), (Charrier-Mojtabi and Mojtabi etal, 1979), (Date, 1986), (Kuhen \& Golstein, 1976) and (Akbar et-al, 1985). Numerical studies of free convection in vertical annulus enclosures are found in the works of (Schwab \& De Witt, 1970), (Kubair \& Simha, 1982) (Keyhani et-al, 1983) and (Prasad \& Kulacki, 1985). Many investigators interested in the study of eccentric annular enclosures (Shue et-al, 2001) or elliptic cylinders (Lee and Lee, 1981). Most of the studies available are for high aspect ratio.

The present paper considers the axisymmetric flow regime in a vertical annulus enclosure Fig. (1) whose surface temperatures are kept isothermal and with Boussinesq approximation being made to the governing equations.

## MATHEMATICAL FORMULATION

The problem considered are both the transient and steady state, twodimensional axisymmetric laminar convection of a Boussinesq fluid initially at rest and a uniform temperature is assumed in the mathematical model for the system shown in Fig. (1). The vertical cylindrical surfaces are considered to be perfect conductors of heat with the inner wall temperature (Ti) greater than that of the outer wall (To). Both top and bottom surfaces of the enclosure are considered to be perfect insulators with a rigid and motionless bounding surfaces. The dimensionless equations of continuity, momentum and energy are (Schwab \& De Witt, 1970):
$(1 / \mathrm{R})[\mathrm{R}(\partial \mathrm{U} / \partial \mathrm{R})]+(\partial \mathrm{V} / \partial \mathrm{Z})=0$
$\left(\partial \mathrm{U} / \partial \mathrm{T}_{\mathrm{M}}\right)+\mathrm{U}(\partial \mathrm{U} / \partial \mathrm{R})+\mathrm{V}(\partial \mathrm{U} / \partial \mathrm{Z})=-(\partial \mathrm{P} / \partial \mathrm{R})+\operatorname{Pr}\left[\partial / \partial \mathrm{R}\left\{\left({ }^{1} / \mathrm{R}\right)(\partial \mathrm{RU} / \partial \mathrm{R})\right\}+\left(\partial^{2} \mathrm{~V} / \partial \mathrm{Z}^{2}\right)\right]$
$\left(\partial \mathrm{V} / \partial \mathrm{T}_{\mathrm{M}}\right)+\mathrm{V}(\partial \mathrm{V} / \partial \mathrm{R})+(\partial \mathrm{V} / \partial \mathrm{Z})=-(\partial \mathrm{P} / \partial \mathrm{Z})+\operatorname{Pr}\left[(1 / \mathrm{R})\left(\partial / \partial \mathrm{R}\{\mathrm{R}(\partial \mathrm{V} / \partial \mathrm{R})\}+\left(\partial^{2} \mathrm{~V} / \partial \mathrm{Z}^{2}\right)\right]\right.$
$\left(\partial \Theta / \partial \mathrm{T}_{\mathrm{M}}\right)+\mathrm{U}(\partial \Theta / \partial \mathrm{R})+\mathrm{V}(\partial \Theta / \partial \mathrm{Z})=\left({ }^{1} / \mathrm{R}\right)[(\partial / \partial \mathrm{R})\{\mathrm{R}(\partial \Theta / \partial \mathrm{R})\}]+\left(\partial^{2} \Theta / \partial \mathrm{Z}^{2}\right)$
The vorticity-stream function formulation is applied in order to avoid direct determination of the lateral variations of pressure. The conservation equations then become:

Vorticity:
$\left(\partial \omega / \partial \mathrm{T}_{\mathrm{M}}\right)+(\partial \mathrm{U} \omega / \partial \mathrm{R})+(\partial \mathrm{V} \omega / \partial \mathrm{Z})=\operatorname{Ra}_{\mathrm{d}} \operatorname{Pr}(\partial \Theta / \partial \mathrm{R})+\operatorname{Pr}[(\partial / \partial \mathrm{R})\{(1 / \mathrm{R})(\partial \mathrm{R} \omega / \partial \mathrm{R})\}(5)$
Stream function:
Number4 Volume13 December 2007 Journal of Engineering

$$
\begin{equation*}
\nabla^{2} \psi=-\omega=(1 / \mathrm{R})\left[\left(\partial^{2} \psi / \partial \mathrm{R}^{2}\right)-(1 / \mathrm{R})(\partial \psi / \partial \mathrm{R})+\left(\partial^{2} \psi / \partial \mathrm{Z}^{2}\right)\right] \tag{6}
\end{equation*}
$$

Energy:
$\left({ }^{1} / \mathrm{R}\right)(\partial \mathrm{RU} \Theta / \partial \mathrm{R})+(\partial \mathrm{V} \Theta / \partial \mathrm{Z})=\left({ }^{1} / \mathrm{R}\right)[(\partial / \partial \mathrm{R})\{\mathrm{R}(\partial \Theta / \partial \mathrm{R})\}]+\left(\partial^{2} \Theta / \partial \mathrm{Z}^{2}\right)$
The initial and boundary conditions are:

$$
\begin{array}{rll}
\text { For } & \mathrm{T}_{\mathrm{M}}=0, & \omega=\psi=\mathrm{U}=\mathrm{V}=0 \\
& , \quad \Theta_{\mathrm{i}}=1, \Theta_{0}=1 \quad \text { (no slip condition) } \\
\text { For } \quad \mathrm{T}_{\mathrm{M}}>0, & \psi=\partial \psi / \partial \mathrm{n}=0, \partial \Theta / \partial \mathrm{Z}=0 \\
& & \omega_{\text {Vertical wall }}=-(1 / \mathrm{R})\left(\partial^{2} \psi / \mathrm{Z}^{2}\right) \quad, \omega_{\text {horizontal wall }}=-(1 / \mathrm{Z})\left(\partial^{2} \psi / \mathrm{R}^{2}\right)
\end{array}
$$

## NUMERICAL SOLUTION OF THE GOVERNING EQUATIONS

An analytic solution cannot be found for a set of equations because of the complexity of those characterizing the cavity problem, and thus they must be integrated numerically by finite difference techniques. In this study, the governing equations which are expressions of conservation of mass, momentum and thermal energy are non-dimensionalized. A two-dimensional explicit finite difference technique was used to solve the transient behavior of the fluid and the heat transfer until the steady state is reached by marching out in time step $\Delta \mathrm{T}_{\mathrm{M}}$. A forward difference technique may used to convert the convection terms in the energy and vorticity transport equations to an algebraic terms and in concern of diffusion terms, the central difference technique may used. To get numerical stability, the forward difference technique is applied when the mean value of the velocity is positive and the backward difference technique is applied when the mean velocity value is negative, so the method choice depends on the flow direction. To solve the stream function equation the Gauss Siedel method used with the successive over relaxation method to make earlier convergence. A numerical stability occurred when the time step $\Delta \mathrm{T}_{\mathrm{M}}$ is greater than $\left(\Delta \mathrm{T}_{\mathrm{M}}\right)_{\text {max. }}$, which depends on $\mathrm{Ra}_{\mathrm{d}}$ and grid spacing. In this study the suitable $\Delta T_{M}$ was found to be ( $\Delta T_{M} \leq 0.0001$ ) for fixed $\mathrm{Ra}_{\mathrm{d}}$. The main steps of the solution procedure can be listed as follow:

1. The boundary and initial conditions are specified for the dependent variables.
2. The discretized temperature equation is solved to obtain the updated temperature field.
3. Vorticity at all interior grid points was similarly advanced from using the updated temperature field.
4. Stream function at all interior grid points was updated with the updated vorticity field.
5. Local Nusselt number computed and the method of successive over relaxation was employed to obtain the new stream function at each grid point. Convergence was assumed whenever any two successive iterations was less than $10^{-4}$.
6. Total heat transfer calculated depending on local Nusselt number.
7. Steps (1-6) were repeated until the magnitude of the error ratio $(\varepsilon)$ did not change by more than $10^{-4}$.

## RESULTS AND DISCUSSION

The difference equations of this study were solved on a digital computer using FORTRAN 95 program and the Tec Plot program used to plot the isotherm and streamline contours. The results are expressed in the transient region until reaching steady state where $\tilde{\mathrm{N}} \mathrm{u}_{\mathrm{i}}$ will be constant with time.

## Transient Results

## Grid Spacing

The time steps used depend on $\mathrm{Ra}_{\mathrm{d}}$ as shown in Table (1), and the grid spacing which was found to give an adequate representation of the results for $\mathrm{Ra}_{\mathrm{d}}=10^{3}$ and $10^{4}$ was $(1 / 10)$ and for $\mathrm{Ra}_{\mathrm{d}}=10^{5}$ and $10^{6}$ the grid spacing were $(1 / 20)$ and $(1 / 30)$ respectively.
Table (2) explain the best values for nodes number ( N ) in radial direction and (M) in vertical direction for $\left(10^{3} \leq R a_{d} \leq 10^{6}\right)$.

## Flow and Isotherm Patterns

Figs. (2-13) show typical results obtained for vertical annuli with Rayleigh number $\left(10^{3} \leq R \mathrm{Ra}_{\mathrm{d}} \leq 10^{6}\right)$, for different time steps. The fluid near the outer (colder) cylinder is heavier and is moving downward while the relatively lighter fluid near the inner (hotter) cylinder is moving upward and with the increase of $R a_{d}$ a slightly vertical displaced occurred towards the top of the annulus so the convection regime appears clearly as shown in Figs. (2, 3, 4 and 5 ).

The temperature gradient across the cavity is horizontal with conduction profiles being vertical lines traversing the entire length of the cavity as indicated in Fig.(6) and then start to develop and indicate more inclination in its lines while the slope of lines near (cold wall) is small because the velocity is decreased Fig.(7, 8 and 9). When $\mathrm{Ra}_{\mathrm{d}}$ approaches $10^{3}$, large temperature gradients grow near the vertical wall giving rise to the formation of thermal boundary layers and fluid velocities sufficient to form hydrodynamic boundary layer. A unicellular flow pattern is generated in the enclosure. It is noticed that the maximum heat transfer, indicated by closely spaced isotherms, is located at the top of the cavity for the outer cylinder and at the bottom for the inner one.

As a consequence of the symmetry and the continuity, the resulting fluid motion inside the half cavity consists of one rotating vortex as shown in Fig. (10) when the time increasing a multi small vorticity will be appeared

In Figs. (11, 12 and 13) it is seen that a small secondary vorticity appears in the bottom and become smaller with time increasing where a start of forming of a secondary vorticity near the outer cylinder will happened which will be grow with the increasing of fluid velocity.

## Temperature Distribution and Local Nusselt Number

Fig. (14) shows the temperature variation versus $\mathrm{Ra}_{\mathrm{d}}$ for a gap width ( $\mathrm{z}=0.5$ ). In the thermal boundary layer adjacent to the outer cylinder, it is seen that the temperature gradient increases considerably and the trend is opposite near the inner cylinder. This is probably due to higher heat transfer by angular convection flow rather than radial one.
A correlation of $\left(\tilde{N} u_{i}\right)$ with respect of $R a_{d}$ was set up which is given as:
$\tilde{N} u_{i}=0.4134 * \operatorname{Ra}_{\mathrm{d}}{ }^{0.287}$

## Steady State Results

Heat transfer rate can be calculated at a steady state when the average Nusselt number ( $\tilde{N} u_{i}$ ), reach a constant value with time as shown in Fig. (15).
Steady state streamlines and the isotherms for $\mathrm{Ra}_{\mathrm{d}}$ ranging within $\left(10^{3}-10^{6}\right)$ are explained in Fig. ( $\mathbf{1 6} \mathbf{a} \& \mathbf{~ b}$ ) and Fig. $\mathbf{( 1 7} \mathbf{a} \& \mathbf{~ b}$ ) respectively and the vorticity lines are explained in Fig.(18 a\& b) which shows the multi-cellular flow regime except at $\left(\mathrm{Ra}_{\mathrm{d}}>10^{5}\right)$, where single vorticity appears.
A reasonable agreement between the present work results and the previous researches are shown in Fig. (19).

## CONCLUSIONS

The natural convection of a mass of water contained between two concentric cylinders has been investigated numerically.
The results obtained in the present study may be summarized as follows:

1. The basic operation for heat transfer is conduction for $\left(\mathrm{Ra}_{\mathrm{d}} \leq 10^{3}\right)$ and convection for $\left(\mathrm{Ra}_{\mathrm{d}}>10^{3}\right)$.
2. For the unsteady state the streamlines shows a single cell form except at $\left(\mathrm{Ra}_{\mathrm{d}}\right.$ $=10^{5}$ ) where it shows a bicellular form.
3. The time of reaching steady state decreasing with increase of $\mathrm{Ra}_{\mathrm{d}}$ as shown in Fig. (15) because the increasing of $\mathrm{Ra}_{\mathrm{d}}$ cause an increase of liquid acceleration according to buoyancy force increasing.
4. Fig. (17) shows that the heat transfer operation can be divided into three regions, the first is that of heat transfer by conduction which extended to $\left(\mathrm{Ra}_{\mathrm{d}}=10^{3}\right)$ where $\left(\mathrm{N}_{\mathrm{i}}=3\right)$ and it is considered to be the start of convection region. The second region is transition region until plume region is appeared and it's ranged is $\left(10^{3} \leq R a_{d} \leq 10^{4}\right)$. Third region is the plume region where $\left(\operatorname{Ra}_{\mathrm{d}} \geq 10^{5}\right)$.
