# Simultaneous Mass, Heat and Momentum Transfer in <br> an Adiabatic Packed Bed Reactor 

Ban A.Ahmed, Sattar J.Hussen ,Saba A.Yosif
Petroleum Research \& Development Centre,Iraq

## Abstract: <br> $\mathbf{P}_{\text {rocess }}$ modeling or computer

 simulation is one of the most important studies which gives the engineer a whole description about certain processes including all the mathematical relationships that are relating the process variables.Transport phenomena on fixed bed reactor was studied because of their importance and their effects on the catalyst performance in all chemical reactions

Simultaneous mass , heat and pressure drop were studied and all the process variables such as temperature, rate of reaction , pressure along length of the reactor were calculated and the data obtained from the mathematical package showed that with the increase the reaction temperature the process
production , rate of reaction and pressure drop will increase.

Key words: mass transfer heat transfer fixed bed reactor pressure drop catalytic reactor .

## Introduction:

One of the most important and critical processes in petroleum refineries is the catalytic process in which we get more valuable products used in industry. The mathematical modeling for such processes will be very important to evaluate and to understand the performance and how to overcome
the operating problems that may occurs. Many factors are affecting any processes such as the operating conditions, catalyst types and its properties.

So in our model we first try to study these factors theoretically and how it affect the results we get, and second to compare the actual data obtained from refinery with our model and how does the data deviate in these two cases. This report deals with the first case and in our future work we shall study the second case [1,2].

## Energy Balance ;

Our attention was focused on heat effects in chemical reactors. The basic design equations rate laws and stoichiometric relationships will be derived for non-isothermal reactor. An energy balance will be carried out on the open system as shown in figure(1) [3] .

Figure (1) Energy balance on an open system: schematic.
[flow rate of heat to the system from the surrounding] - [rate of work done by the system on the surrounding] + [rate of energy added to the system] - [rate of energy leaving the system] $=$ [rate of accumulation of energy with in the system]

$$
\begin{equation*}
Q-w^{\circ}+\left.\sum E_{i} * F_{i}\right|_{\text {in }}-\left.\sum E_{i} * F_{i}\right|_{\text {out }}=\frac{d E_{\text {sys. }}}{d t} \tag{1}
\end{equation*}
$$

## Evaluating the Work Term :

The work can be classified into flow work and shaft work. Flow work is the work that is necessary to get the mass into and out of the system and the shaft work could be produced from a stirrer in a CSTR or a turbine in a PFR. as in eq. below [3]
$w^{o}=-\left.\sum F_{i} * p * V_{i}\right|_{\text {in }}+\left.\sum F_{i} * p * V_{i}\right|_{\text {out }}+w_{s}$
sub eq. 2 in 1 we get
$Q-w_{s}+\left.\sum F_{i} *\left(E_{i}+P * V_{i}\right)\right|_{\text {in }}-\left.\sum F_{i} *\left(E_{i}+P * V_{i}\right)\right|_{\text {out }}=\frac{d E_{s y s .}}{d t}$

The energy $E_{i}$ is the sum of the internal energy $\left(U_{i}\right)$, kinetic energy $\left(u_{i}{ }^{2} / 2\right)$,and the potential energy $\left(\mathrm{gz}_{\mathrm{i}}\right)$. In almost all chemical reactor the kinetic, potential energy terms are negligible in comparison with in the enthalpy so the energy equal to the internal energy [3, 4]

$$
\begin{equation*}
E_{i}=U_{i} \tag{4}
\end{equation*}
$$

The enthalpy (Hi) is defined in terms of the internal energy and the product PV .as below :-
$\mathrm{H}_{\mathrm{i}}=\mathrm{U}_{\mathrm{i}}+\mathrm{P} * \mathrm{~V}_{\mathrm{i}} \longrightarrow \mathrm{U}_{\mathrm{i}}=\mathrm{H}_{\mathrm{i}}-\mathrm{P} * \mathrm{~V}_{\mathrm{i}}$
sub eq. 5 into eq. 3

$$
\begin{equation*}
Q-w_{s}+\left.\sum F_{i} * H_{i}\right|_{\text {in }}-\left.\sum F_{i} * H_{i}\right|_{\text {out }}=\frac{d E_{\text {sys. }}}{d t} \tag{6}
\end{equation*}
$$

Eq. 6 describes the Overall Energy Balance on a flow reactor.
Assumptions:-
$\frac{\text { Assumptions:- }}{* \text { Steady state conditions, }} \quad \frac{d E_{s y s .}}{d t}=0$
Reaction is carried out is first order in a packed bed reactor.

* Adiabatic condition.
$Q=o$
* Neglected the work done. $\quad W_{s}=0$

So eq. 6 become:-

$$
\left.\sum F_{i} * H_{i}\right|_{i n}-\left.\sum F_{i} * H_{i}\right|_{o u t}=0
$$

The express the molar flow rate in terms of conversion:-

For reaction $\mathrm{A} \longrightarrow \mathrm{B}$

$$
\begin{equation*}
F_{i}=F_{A o} *\left(\theta_{i}+v_{1} * \chi\right) \tag{8}
\end{equation*}
$$

So the flow rate for A and B

$$
\begin{gather*}
F_{A}=F_{A O} *(1-\chi) \\
F_{B}=F_{A O} *\left(\theta_{B}+\chi\right) \tag{9}
\end{gather*}
$$

sub. Eq. 9 into eq. 7

$$
\begin{array}{ll}
\text { In } & \sum H_{i^{o}} * F_{i^{o}}=H_{A^{o}} * F_{A^{o}}+H_{B^{o}} * F_{B^{o}} \\
\text { Out } & \sum H_{i} * F_{i}=H_{A} * F_{A}+H_{B} * F_{B}
\end{array}
$$

Subtraction

$$
\begin{aligned}
& H_{A^{o}} * F_{A^{o}}+H_{B^{o}} * F_{B^{o}}-H_{A} \times\left[F_{A^{o}} *(1-\chi)\right]-H_{B} \times\left[F_{A^{o}} *\left(\theta_{B}+\chi\right)\right] \\
& F_{A^{o}} *\left(H_{A^{o}}-H_{A}\right)+F_{A^{o}} * \theta_{B} *\left(H_{B^{o}}-H_{B}\right)-\left[H_{B}-H_{A}\right] * F_{A^{o}} * \chi
\end{aligned}
$$

## $\Delta H_{R}$

Express the enthalpy term:-

$$
\begin{equation*}
H_{i o}-H_{i}=\int_{T_{0}}^{T} c P_{i} * d T \tag{11}
\end{equation*}
$$

sub. eq. 11 and eq. 10 into eq. 7

$$
\left(\int_{T_{o}}^{T} \sum \theta_{i} * c p_{i} * d T\right) * F_{A^{o}}-\Delta H_{R} * F_{A^{o}} * \chi=0 \cdots \cdots .12
$$

Express the heat of reaction term:-

$$
\Delta H_{R}=\Delta H_{R_{(T R)}^{o}}+\int_{T_{R}}^{T} c p_{i} * d T
$$

sub. eq. 13 into eq. 12
$\chi *\left[\left(\Delta \mathrm{H}_{R^{o}(T R)}\right)+\int_{T_{R}}^{T} \Delta c p * d \mathrm{~T}\right]=\int_{T_{o}}^{T} \sum \theta_{i} * c p_{i} * d \mathrm{~T}$
This is the Energy Balance eq. for Adiabatic Packed Bed Reactor (PBR).
Open the brackets on eq. 14

$$
\begin{equation*}
\Delta \mathrm{H}_{R^{o}(T R)} * \chi+\int_{T_{R}}^{T} \Delta c p * d \mathrm{~T} * \chi=-\int_{\mathrm{T}_{o}}^{\mathrm{T}} \sum \theta_{i} * c p_{i} * d \mathrm{~T} \tag{15}
\end{equation*}
$$

Differentiate eq. 15 with respect to V

$$
\Delta \mathrm{H}_{R^{o}(T R)} * \frac{d \chi}{d V}+\int_{T_{R}}^{\mathrm{T}} \Delta c p * d \mathrm{~T} * \frac{d \chi}{d V}+\chi * \Delta c p_{i} * \frac{d \mathrm{~T}}{d V}=-\theta_{i} * c p_{i} * \frac{d \mathrm{~T}}{d V}
$$

$\qquad$

Rearrange eq. 16
$-\left(\Delta \mathrm{H}_{R^{o}(T R)}+\int_{T_{R}}^{\mathrm{T}} \Delta c p * d \mathrm{~T}\right) * \frac{d \chi}{d V}=\left(\sum \theta_{i} * c p_{i}+\Delta c p_{i} * \chi\right) * \frac{d \mathrm{~T}}{d V}$

Eq. 17describes the change of temperature and conversion across the volume of a PBR.

## Mole Balance:

We will now perform the general mole balance equation for $\operatorname{PBR}$ reactor as shown in figure 2. [3, 4]

PFR

$$
F_{i(x)}+F_{i(x+\Delta x)}+r_{i} * \Delta V=\frac{d N_{i}}{d t}
$$

## Assumptions:

Steady state conditions, $\quad \frac{d N_{i}}{d t}=\mathrm{O}$

* Reaction that is carried out is a first order in a packed bed reactor.

After applying the assumptions

$$
\begin{equation*}
F_{i(x)}+F_{i(x+\Delta x)}+r_{i} * \Delta V=0 \tag{19}
\end{equation*}
$$

The volume $\Delta \mathrm{V}$ is the product of the cross sectional area A of the reactor length $\Delta \mathrm{x}$.

$$
\Delta V=A * \Delta x \quad \ldots \ldots \ldots . .20
$$

Sub eq. 20 into eq. 19 and divide by $\Delta \mathrm{x}$ and then taking the limit as $\Delta \mathrm{x}$ approaches zero

$$
\frac{d F_{i}}{d V}=-r_{i} \ldots \ldots \ldots . .21
$$

Recall eq. $9 \quad F_{A}=F_{A o} *(1-\chi)$

After differentiate eq. 9 and sub it in eq. 21

$$
\frac{d \chi}{d V}=\frac{1}{F_{\mathrm{A}^{\circ}}} *\left(-r_{A}\right)
$$

Eq. 22 is the Mole Balance eq. on the steady state PBR.
Sub. eq. 22 into eq. 17
$-\left(\Delta \mathrm{H}_{R^{o}(T R)}+\int_{T_{R}}^{T} \Delta c p_{i} * d \mathrm{~T}\right) \times\left(-r_{\mathrm{A}}\right)=F_{\mathrm{A}^{\circ}} *\left(\sum \theta_{i} * c p_{i}+\Delta c p_{i} * \chi\right) * \frac{d \mathrm{~T}}{d V}$
$\qquad$

Arrangement of eq. 23

$$
\frac{d \mathrm{~T}}{d V}=\frac{-\left(\Delta \mathrm{H}_{R^{o}}+\int_{\mathrm{T}_{R}}^{\mathrm{T}} \Delta c p_{i} * d \mathrm{~T}\right) \times\left(-r_{\mathrm{A}}\right)}{F_{\mathrm{A}^{o}} *\left(\sum \theta_{i} * c p_{i}+\Delta c p_{i} * \chi\right)} \quad \ldots \ldots .24
$$

Eq. 14 describes the change on temperature a long the volume of PBR.

## Heat Capacity Calculations:

The form of energy balance in the case where heat capacities are strong functions of temperature over a wide temperature range. Combining equation (24 )with the quadratic form of the heat capacity [5].

$$
\begin{aligned}
& c p_{i}=\alpha_{i}+\beta_{i} * T+\gamma_{i} * T^{2} \ldots \ldots . .25 \\
& \Delta c p_{i}=\Delta \alpha_{i}+\Delta \beta_{i} * \mathrm{~T}+\Delta \gamma_{i} * \mathrm{~T}^{2} \ldots \ldots \ldots .26
\end{aligned}
$$

Sub. Eq. 25, and eq,. 26 into eq. 24 , and integrating :
$\frac{d \mathrm{~T}}{d V}=\frac{-\left[\Delta \mathrm{H}_{R^{o}}+\Delta \alpha_{i} *\left(\mathrm{~T}-\mathrm{T}_{R}\right)+\frac{\Delta \beta_{i}}{2} *\left(\mathrm{~T}^{2}-\mathrm{T}_{R}^{2}\right)+\frac{\Delta \gamma_{i}}{3} *\left(\mathrm{~T}^{3}-\mathrm{T}_{R}^{3}\right)\right] \times\left(-r_{A}\right)}{F_{\mathrm{A}^{o}} *\left[\left(\theta_{i} * \alpha_{i}+\theta_{i} * \beta_{i} * T+\theta_{i} * \gamma_{i} * T^{2}\right)+\chi *\left(\Delta \alpha_{i}+\Delta \beta_{i} * T+\Delta \gamma_{i} T^{2}\right)\right]}$

Eq. 27 describes the Energy Balance for the case of highly Temperature sensitive heat capacities for PBR.

## Pressure Drop:

It is important to predict the drop in pressure for the flow of the fluid through a packed column. In reactor design there is a pressure drop through a packed of
catalyst bed, when there is a liquid phase reactions, the concentration of reactant is insignificantly affected by even relatively large change in the total pressure. Consequently, we can totally ignore the effect of pressure
drop on the rate of reaction when sizing liquid - phase chemical reactors.

However, in gas - phase reactions, the concentration of reacting species is proportional to the total pressure and consequently, proper accounting
for the effect of pressure drop on the reaction system can, in many instances, be a key factoring the success or failure of the reactor operation $[6,7]$.

## Pressure drop \& the Rate Law:

Our attention is focused on the accounting for the pressure drop on the rate law, for gas - phase reactions pressure drop may be very important. [8] For an ideal gas, the concentration of reacting species (I)

$$
\begin{align*}
& C_{i}=\frac{F_{i}}{v_{i}}=\frac{F_{A^{o}} *\left(\Theta_{i}+v_{1} * \chi\right)}{v_{o} *(1+\varepsilon * \chi) *\left(P_{1} / P\right) *\left(T / T_{o}\right)} \\
& C_{i}=\frac{C_{A^{o}} *\left(\Theta_{i}+v_{i} * \chi\right)}{(1+\varepsilon * \chi)} *\left(P / P_{1}\right) *\left(T_{o} / T\right) . .
\end{align*}
$$

Now determine the ratio $\left(\mathrm{P} / \mathrm{P}_{\circ}\right)$ as a function of volume of the reactor to account for pressure drop then combine the concentration, rate law, temperature and design equations in differential form and then solved simultaneously to understand the behavior of reactor First order isomerization of n-hexane reaction is being carried out in a packed bed - reactor [8] ,

The differential form of material balance in term of volume of reactor

$$
\begin{equation*}
F_{A^{\circ}} * \frac{d \chi}{d V}=-r_{A} \tag{29}
\end{equation*}
$$

$$
-r_{A}=k * C_{A} \quad \ldots \ldots \ldots . .30
$$

sub. Eq. 28 into eq. 30,

$$
\begin{equation*}
-r_{A}=k * \frac{C_{A^{\circ}} *\left(\Theta_{i}+v_{1} * \chi\right)}{(1+\varepsilon * \chi)} *\left(P / P_{1}\right) *\left(T_{o} / T\right) \tag{31}
\end{equation*}
$$

sub. Eq. 31 into eq. 29,

$$
\frac{d \chi}{d V}=\frac{k}{F_{A^{o}}} * \frac{C_{A^{\circ}} *\left(\Theta_{i}+v_{1} * \chi\right)}{(1+\varepsilon * \chi)} *\left(P / P_{1}\right) *\left(T_{o} / T\right)
$$

## Pressure Drop Equation:

The most equation used to calculate the pressure drop in a packed of porous bed is the Ergun equation:
$\frac{\partial P}{\partial L}=-\frac{G}{\rho * g * D_{p}} *\left\langle\frac{1-\varphi}{\varphi^{3}}\right\rangle *\left[\frac{150(1-\varphi) * \mu}{D_{p}}+1.75 * G\right]$

The only parameter that varies in eq. 33 is the gas density ( $\rho$ ), and because the reactor is operated at steady state, the mass flow rate at any point down the
reactor (mo) is equal to the entering mass flow rate( m ) (equation of continuity) [7].

$$
m_{o}=m \longrightarrow \rho_{o} * v_{o}=\rho * v \quad \ldots \ldots . .34
$$

Where,

$$
v=v_{o} * \frac{P_{1}}{P} * \frac{T}{T_{o}} * \frac{F_{T}}{F_{T o}} \ldots \ldots .35
$$

So ,

$$
\rho=\rho_{o} \frac{v_{o}}{v}=\rho_{o} * \frac{P}{P_{1}} * \frac{T_{o}}{T} * \frac{F_{T o}}{F_{T}}
$$

Combine eq. 36 with eq. 33

$$
\frac{d P}{d L}=-\frac{G}{\rho_{o} * g * D_{p}} *\left\langle\frac{1-\varphi}{\varphi^{3}}\right\rangle *\left[\frac{150(1-\varphi) * \mu}{D_{p}}+1.75 * G\right] * \frac{P_{1}}{p} * \frac{T}{T_{o}} * \frac{F_{T}}{F_{T o}}
$$

Finally substitute for $\mathrm{F}_{\mathrm{T}} / \mathrm{F}_{\mathrm{TO}}$

$$
\begin{aligned}
& F_{T}=F_{T o}+F_{A o} * \delta * \chi \\
& \frac{F_{T}}{F_{T o}}=\left[1+\left(\frac{F_{A o}}{F_{T o}}\right) * \delta * \chi\right]_{\ldots \ldots .38}
\end{aligned}
$$

$$
\frac{F_{T}}{F_{T o}}=\left[1+y_{A o} * \delta * \chi\right] \quad \longrightarrow \quad \frac{F_{T}}{F_{T o}}=[1+\varepsilon \chi]
$$

Sub. Eq. 39 into eq. 37

$$
\frac{d P}{d L}=-\frac{G}{\rho_{o} * g * D_{p}} *\left\langle\frac{1-\varphi}{\varphi^{3}}\right\rangle *\left[\frac{150(1-\varphi) * \mu}{D_{p}}+1.75 * G\right] * \frac{P_{1}}{p} * \frac{T}{T_{o}} *(1+\varepsilon \chi)
$$

let

$$
\beta=-\frac{G}{\rho_{o} * g * D_{p}} *\left\langle\frac{1-\varphi}{\varphi^{3}}\right\rangle *\left[\frac{150(1-\varphi) * \mu}{D_{p}}+1.75 * G\right]
$$

$$
\begin{equation*}
\frac{d P}{d L}=-\beta * \frac{P_{1}}{p} * \frac{T}{T_{o}} *(1+\varepsilon \chi) \tag{41.}
\end{equation*}
$$

Eq. 41 describes the pressure drop down the PFR.

## Results and Discussions:

After we described the material, heat and momentum transfer through the adiabatic fixed bed reactor we get 3 differential ordinary equations
that we need to solve them simultaneously in order to get how the conversion, temperature and pressure drop varies down the length of the reactor [3].

The equations are shown below

$$
\begin{aligned}
& \frac{d \chi}{d V}=\frac{1}{F_{\mathrm{A}^{\circ}}} *\left(-r_{A}\right) \\
& \frac{d \mathrm{~T}}{d V}=\frac{-\left(\Delta \mathrm{H}_{R^{o}}+\int_{\mathrm{T}_{R}}^{\mathrm{T}} \Delta c p_{i} * d \mathrm{~T}\right) \times\left(-r_{\mathrm{A}}\right)}{F_{\mathrm{A}^{\circ}} *\left(\sum \theta_{i} * c p_{i}+\Delta c p_{i} * \chi\right)} \\
& \frac{d P}{d L}=-\beta * \frac{P_{1}}{p} * \frac{T}{T_{o}} *(1+\varepsilon \chi)
\end{aligned}
$$

To solve these equations a mathematical package is used named "Polymath 5.1" so the equations with initial and final limits with the definition of the explicit equations, constants and the initial operating condition are entered.

After the run of the program, the final report for data that describe the

A plot of a conversion\& temperature along the length of reactor is shown in figures (3),(4).

Fig. (3) Conversion down the length of fixed bed adiabatic reactor, $T_{\text {o }}$ =573 K \& no pressure drop

Fig. (4) Change in reaction temperature down the length of fixed bed adiabatic reactor, $\mathrm{T}_{\mathrm{o}}=573 \mathrm{~K} \&$ no pressure drop.

In figure $3 \& 4$ it is noticed that the conversion increases down the length of the reactor and because of the reaction is exothermic the temperature will also be increased at
the same inlet reactor temperature.
Also the reaction rate grows up to maximum value near the entrance of the reactor and then begins to stabilized after 1 m of the reactor length as shown in figure(5).[8]

Fig. (5) Rate of reaction down the length of fixed bed adiabatic reactor, $\mathrm{T}_{\mathrm{o}}=573 \mathrm{~K} \&$ no pressure drop.

One way may be needed to decrease the accumulated heat or temperature due to the exothermic reaction by adding a coolant to maintain a certain high conversion and reaction rate for the process [9].
We can see from figures (6) \& (7) that increasing bed pressure will results in compressing the bed then
reducing the voids between the molecules (dense packing).
Moreover fluid resistance to flow will be high; consequently the substance amount that moves forward the active sites of the catalyst will be slight. Accordingly less conversion and low reaction speed will be obtained [6].

Fig. (6) Change in Conversion down the length of Fixed bed adiabatic reactor

Fig. (7) Change in rate of reaction down the length of Fixed bed adiabatic reactor , $\mathrm{T}_{\mathrm{o}}=573 \mathrm{~K}$.

Also we can see that when changing the initial reaction temperature the conversion also increases at a certain operating pressure as shown in figure (8) [10].

Fig. (8) Change in Conversion down the length of fixed bed
adiabatic reactor $\mathrm{P} 1=1$ atm .
figure (9) shows the change in the pressure drop down the length of the reactor, and it's obviously that pressure increases through the bed of the catalyst and many factors are
affecting this pressure such as the fluid mass velocity, porosity of the bed, properties of the reacting fluid and the operating conditions.

All these factor are included in the pressure drop equation (41).

Fig. (9) Change in pressure down the length of Fixed bed adiabatic reactor, $\mathrm{T}_{\mathrm{o}}=573 \mathrm{~K}$.

## Conclusions:

- The pressure drop affects the reaction rate, so by increasing the inlet pressure the rate of reaction will be decreased from 38 to 13 mole / sec. $\mathrm{m}^{3}$ when the pressure drop is changed from 0 to 3 atm .
- The conversion will be increased from $80 \quad-90 \quad \%$ by increasing the reaction temperature
from $573-600 \mathrm{~K}$ at 1 m length of the reactor.
- The effect of time on operation must be considered on the future work by studying the effect on unsteady state condition on the reactor such as ( rate of reaction, temperature and on the pressure drop)

## Nomenclature

| Symbols | Notations |
| :---: | :---: |
| A | $=$ Cross sectional area of reactor $\left(\mathrm{m}^{2}\right)$. |
| $\mathrm{C}_{\text {Ao }}$ | $=$ Initial concentration (mole $/ \mathrm{m}^{3}$ ). |
| $\mathrm{C}_{\text {Pi }}$ | $=$ Heat capacity of species i at temperature T ( $\mathrm{J} / \mathrm{mole} . \mathrm{K})$. |
| $\mathrm{D}_{\mathrm{p}}$ | $=$ Diameter of particles in bed (m). |
| $\mathrm{E}_{\mathrm{i}}$ | $=$ Energy of species $\mathrm{i}(\mathrm{J} / \mathrm{s})$. |
| $E_{\text {system }}$ | $=$ Total energy of the system ( $\mathrm{J} / \mathrm{s}$ ) . |
| $\mathrm{F}_{\text {A }}$ | $=$ Molar flow rate of species A (mole/s). |
| $\mathrm{F}_{\text {B }}$ | $=$ Molar flow rate of species B (mole/s). |
| $\mathrm{F}_{\mathrm{AO}}$ | $=$ Initial molar flow of species A (mole/s). |
| $\mathrm{F}_{\mathrm{BO}}$ | $=$ Initial molar flow of species i (mole/s). |
| $\mathrm{F}_{\mathrm{i}}$ | $=$ Molar flow rate of species i (mole/s). |
| $\mathrm{F}_{\text {io }}$ | $=$ Initial molar flow of species i (mole/s). |
| $\mathrm{F}_{T}$ | $=$ Total molar flow (mole/s). |
| $\mathrm{F}_{\text {T0 }}$ | $=$ Initial total molar flow (mole/s). |
| G | $=$ Superficial mass velocity ( $\mathrm{Kg} / \mathrm{m}^{2} . \mathrm{s}$ ) . |
| g | $=$ Conversion constant. |
| $\mathrm{H}_{\text {A }}$ | $=$ Enthalpy of species A at temperature T ( $\mathrm{J} / \mathrm{mole}$ ). |
| $\mathrm{H}_{\text {B }}$ | $=$ Enthalpy of species B at temperature T ( $\mathrm{J} / \mathrm{mole})$. |

| $\mathrm{H}_{\mathrm{i}}$ | $=$ Enthalpy of species i at temperature $\mathrm{T}(\mathrm{J} / \mathrm{mole})$. |
| :---: | :---: |
| $\mathrm{H}_{\text {io }}$ | $=$ Enthalpy of species i at temperature $\mathrm{T}_{0}(\mathrm{~J} / \mathrm{mole})$ |
| $\mathrm{H}_{\mathrm{i}}{ }^{\text {O}}$ | $=$ Enthalpy of formation of species i at temperature $\mathrm{T}_{\mathrm{R}}(\mathrm{J} / \mathrm{mole})$ |
| к | $=$ Reaction rate constant ( $\mathrm{s}^{-1}$ ). |
| L | $=$ Length of reactor ( m ) . |
| m | $=$ Mass flow rate ( $\mathrm{Kg} / \mathrm{s}$ ) . |
| $\mathrm{m}_{0}$ | $=$ Entering molar flow rate ( $\mathrm{Kg} / \mathrm{s}$ ). |
| $\mathrm{N}_{\mathrm{i}}$ | $=$ Number of mole of species i (mole). |
| P | $=$ Partial pressure (atm). |
| $\mathrm{P}_{1}$ | $=$ Initial pressure (atm). |
| Q | $=$ Heat flow from the surrounding to the stream ( $\mathrm{J} / \mathrm{s}$ ). |
| $r_{\text {A }}$ | $=$ Rate of generation of species $\mathrm{A}\left(\mathrm{mole} / \mathrm{s} . \mathrm{m}^{3}\right)$. |
| $\mathrm{r}_{\mathrm{i}}$ | $=$ Rate of generation of species $\mathrm{i}\left(\mathrm{mole} / \mathrm{s} . \mathrm{m}^{3}\right)$. |
| T | $=$ Temperature ( K ). |
| To | $=$ Initial temperature ( K ). |
| $\mathrm{T}_{\mathrm{R}}$ | $=$ Standard temperature 298 K . |
| $u_{i}$ | $=$ Internal energy of species i $(\mathrm{J} / \mathrm{mole})$. |
| V | $=$ Volume of reactor $\left(\mathrm{m}^{3}\right)$. |
| $v$ | $=$ Volumetric flow rate ( $\mathrm{m}^{3} / \mathrm{s}$ ). |
| $v_{1}$ | $=$ Stoichiometric coefficient. |

```
\(v_{0} \quad=\quad\) Initial volumetric flow rate \(\left(\mathrm{m}^{3} / \mathrm{s}\right)\).
\(w^{o}=\) Flow work (J/s).
\(w_{s} \quad=\quad\) Shaft work \((\mathrm{J} / \mathrm{s})\).
\(\chi=\) Conversion.
\(x \quad=\) Distance (m).
\(\mathrm{y}_{\mathrm{A}}=\) Ratio of \(\mathrm{F}_{\mathrm{AO}} / \mathrm{F}_{\mathrm{TO}}\)
\(\Theta_{i} \quad=\) Ratio of the number of mole of species i initially (entering) to the
        number of moles of \(A\) initially (entering).
\(\Theta_{B} \quad=\) Ratio of the number of mole of species \(B\) initially (entering) to the
        number of moles of A initially (entering).
\(\Delta H_{R} \quad=\) Heat of reaction at any \(T(J / m o l e)\).
\(\Delta \mathrm{H}_{\mathrm{R}}{ }^{0}=\) Slandered heat of reaction at \(298{ }^{\circ} \mathrm{K}(\mathrm{J} / \mathrm{mole})\).
```

## Greek Symbols

```
\(\varphi \quad=\) Porosity of the bed.
\(\mu \quad=\) Fluid viscosity (kg/m.s).
\(\rho \quad=\) Density of the fluid \(\left(\mathrm{kg} / \mathrm{m}^{3}\right)\).
\(\mathrm{Y}=\) Parameter in heat capacity.
\(\beta_{\mathrm{i}} \quad=\) Parameter in heat capacity.
\(\beta=\) Constant on pressure drop equation.
\(\alpha_{i} \quad=\) Parameter in heat capacity.
```

## Calculated values of the DEQ variables

| Variable | initial value | minimal value | maximal value | final value |
| :---: | :---: | :---: | :---: | :---: |
| L | 0 | 0 | 1.7 | 1.7 |
| $T$ | 600 | 600 | 686.12897 | 686.12897 |
| $\boldsymbol{X}$ | 0 | 0 | 0.8864842 | 0.8864842 |
| $p$ | 1 | 0.9142779 | 1 | 0.9142779 |
| $k$ | 9.6141882 | 9.6141882 | 19.257226 | 19.257226 |
| Fao | 1.2 | 1.2 | 1.2 | 1.2 |
| Cp1 | 91.688 | 91.688 | 98.397328 | 98.397328 |
| Cp2 | 2.668 | 2.668 | 2.7597932 | 2.759095 |
| Cao | 6.08 | 6.08 | 6.08 | 6.08 |
| T0 | 600 | 600 | 600 | 600 |
| TR | 298.15 | 298.15 | 298.15 | 298.15 |
| HR | -9501.7539 | -9501.7539 | -9214.9245 | -9214.9245 |
| p1 | 2 | 2 | 2 | 2 |
| Ac | 0.045 | 0.045 | 0.045 | 0.045 |
| ra | 24.355943 | 4.4275751 | 24.355943 | 4.4275751 |
| B | 0.0221 | 0.0221 | 0.0221 | 0.0221 |

## ODE Report (RKF45)

Differential equations as entered by the user

$$
[1] \mathbf{d}(\mathbf{T}) / \mathbf{d}(\mathbf{L})=\left(\mathrm{A}^{*} \mathbf{r}_{\mathrm{A}}\right) *((-1) * \mathbf{H R}) /\left(\mathbf{F}_{\mathrm{A}}{ }^{\left.\mathbf{o}^{*} *\left(\mathbf{C p}_{1}+\mathbf{X} * \mathbf{C} p_{2}\right)\right)}\right.
$$

[2] $\mathbf{d}(\mathbf{X}) / \mathbf{d}(\mathbf{L})=\left(A^{*} \mathbf{r}_{\mathrm{A}}\right) / \mathbf{F}_{\mathrm{A}}{ }^{0}$
[3] $d(p) / d(L)=-1.0 * B *\left(p_{1} / p\right) *\left(T / T_{0}\right)$

Explicit equations as entered by the user
[1] $k=2433.291 * \exp (-3320.256 / T)$
[2] $\mathrm{FAo}=1.2$
[3] $\mathrm{Cp} 1=17.84+0.17 * \mathrm{~T}-\mathbf{0 . 0 0 0 0 8 9 *}\left(\mathrm{T}^{\wedge} 2\right)+\mathbf{0 . 0 0 0 0 0 0 0 1 8 * ( \mathbf { T } ^ { \wedge } 3 )}$
[4] Cp2 $=-9.02+0.043 * T-0.00005 *\left(T^{\wedge} 2\right)+0.000000018 *\left(T^{\wedge} 3\right)$
[5] $\mathrm{CAo}=6.08$
[6] $\mathbf{T 0}=\mathbf{6 0 0}$
[7] TR = 298.15
[8] HR = $-10125.3+\left(-9.02385 *(T-T R)+0.022 *\left(\left(T^{\wedge} 2\right)-\left(T R^{\wedge} 2\right)\right)-1.67 e-5^{*}\left(\left(T^{\wedge} 3\right)-\right.\right.$
$\left.\left.\left(T^{\wedge} 3\right)\right)+0.0000000045 *\left(\left(T^{\wedge} 4\right)-\left(T R^{\wedge} 4\right)\right)\right)$
[9] $\mathbf{p 1}=\mathbf{2}$
[10] $\mathrm{A}=\mathbf{0 . 0 4 5}$
[11] $\mathbf{r a}=\left(\mathrm{k}^{*} \mathbf{C A o} / \mathbf{F A o}\right)^{*}(\mathbf{1 - X}) *(\mathbf{T 0} / \mathbf{T}) *(\mathrm{p} / \mathrm{p} 1)$
[12] $B=0.0221$

## Comments

$[1] d(T) / d(L)=(A * r A) *((-1) * H R) /\left(\mathbf{F A o}^{*}(\mathbf{C p} 1+X * \mathbf{C p 2})\right)$
energy balance eq.
$[2] \mathbf{d}(\mathbf{X}) / \mathbf{d}(\mathbf{L})=\left(A^{*} \mathbf{r A}\right) / \mathbf{F A o}$
rate eq.[mole balance
$[3] d(p) / d(L)=-1.0 * B *(p 1 / p) *(T / T 0)$
pressure drop eq.
$[4] \mathbf{k}=\quad 2433.291 * \exp (-3320.256 / T)$
rate constant eq.
[5] FAo = 1.2
molar flow rate mole/sec
[6] Cp1 $=17.84+0.17 * T-0.000089 *\left(T^{\wedge} 2\right)+0.000000018 *\left(\mathbf{T}^{\wedge} 3\right)$
summation of heat capacity
[7] Cp2 $=\quad-9.02+0.043 * T-0.00005 *\left(T^{\wedge} 2\right)+0.000000018 *\left(T^{\wedge} 3\right)$
delta specific heat capacity of reactant and product
[8] $\mathrm{CAo}=\quad 6.08$
intial concentration of reactant, mole $/ \mathrm{m}^{\wedge} 3$
[9] $\mathbf{T 0}=600$
inlet tepmrature of reactant
[10] TR =
298.15
referance temprature
[11] HR $=\quad-10125.3+\left(-9.02385 *(T-T R)+0.022 *\left(\left(T^{\wedge} 2\right)-\left(T R^{\wedge} 2\right)\right)-1.67 \mathrm{e}-5^{*}\left(\left(T^{\wedge} 3\right)-\right.\right.$
$\left.\left.\left(T^{\wedge}{ }^{\wedge}\right)\right)+0.0000000045 *\left(\left(T^{\wedge} 4\right)-\left(T^{\wedge} 4\right)\right)\right)$
heat of reaction
$[12] \mathrm{ra}=\left(\mathrm{k}^{*} \mathbf{C a o} / \mathbf{F a o}\right) *(1-\mathrm{X}) *(\mathbf{T} 0 / \mathbf{T}) *(\mathrm{p} / \mathrm{p} 1)$

## rate equation

[13] Ac $=0.045$
cross sectional area of the reactor
[14] p1 = 2
intial pressure

Independent variable
variable name : $L$
initial value : 0
final value : 1.7

## Precision

Step size guess. $h=0.000001$
Truncation error tolerance. $\mathbf{e p s}=\mathbf{0 . 0 0 0 0 0 1}$

## General

number of differential equations: 3
number of explicit equations: 12
