## الخلاصة

تحولات فورير السريعة هي طريقة قوية للتحويل لاستخراج خصائص مناسبة لتمييز الوجوه. بعد تطبيق
متحولات فورير السريعة (FFT) على صورة الوجه الكلية بعض المعاملات يتم اختيارها لبناء خصائص معينة. في
بعض الحالات، المعاملات ذات التزدد الواطئ سوف تهمل لموازنة او لمعادلة التباين الواضح حيث ان معامل القوة
لكل المعاملات هي غير متشابهة او متساوية وبعض هذه المعاملا ت يمكن تمييزها عن غبرها من المعاملات،
حيث يمكننا تحقيق معدل تمييز عالي وصحيح بواسطة استخدام معاملات القوة.
في هذا البحث، تم ايجاد معامل القوة للصورة بحيث تؤخذ الصفات المؤثرة في الصورة وتخزن هذه القيم
او (الصفات) في قاعدة بيانات عملية اختيار معامل قوة مختلفة (اعلى 50 فيمة) نؤكد من نجاح الطريقة المقترحة،
ونستخدم هذه القيم او (الصفات) كاساس للمقارنة مع قيم او (صفات) اخرى جديدة مراد خزنها في قاعدة البيانات.

#### Abstract

Fast Fourier Transform (F.F.T) is a powerful transform to extract proper features for face recognition. After applying FFT to the entire face images, some of the coefficients are selected to construct feature. In some cases, the low-frequency coefficients are discarded in order to compensate variations. Since the discrimination power of all the coefficients is not the same and some of them are discriminant than other. So we can achieve a higher recognition rate by using discriminant coefficients (DCs).The proposed approach is data-dependent and is able to find discriminator power ( Dp ) for each image, (the higher 50 value) and store these values in database. The selection of various coefficients confirm the success of the proposed approach. These coefficients are used as a basis for comparison with other attributes store in database.

## 1-Introduction

As one of the most successful applications of image analysis and understanding, face recognition. Face recognition has recently received significant attention, especially during last few years [1]. Activities in this field come from its applications in different areas such as security and surveillance, commercial and law enforcement. Ability for implementation in real time has intensified the attention to this field. Although research in the field of face recognition is active over 30 years and considerable successes in face recognition system have been achieved, still there are unsolved problem in it. Illumination variation, rotation and facial expression are the basic existing challenges in this area [2]. However, frequency domain analysis methods such as Fast Fourier transform (FFT), have been adopted in face recognition. Frequency domain analysis methods transform the image signals from spatial domain to frequency domain and analyze the features in frequency domain. Only limited low-frequency components which contain high energy are selected to represent the image [3].

In this paper, the high value of discriminator power ( Dp ) means high discrimination ability of the corresponding coefficient. In other words, it is expected to gain the maximum recognition rate by using the coefficient that has the maximum discriminator coefficients. This method has been tested on a database of facial image and achieves a good performance.

## 2- Grayscale Image

Grayscale digital images are referred to as monochrome, or one-color, images. They contain brightness information only, no color information. The number of bits used for each pixel determine the number of different brightness levels available. The typical image contains 8 bits/pixel data, which allows us to have 256 (0 255) different brightness (gray) levels. This representation provides more than adequate brightness resolution, in term of the human visual system's requirements, and provides a "noise margin" by allowing for approximately twice as many gray levels as required. This noise margin is useful in real-world applications because of the many different types of noise (false information in the signal) inherent in real system. Additionally, the 8 -bit representation is typical due to the fact that the byte, which corresponds to 8 -bits of data, is the standard small unit in the world of digital computers [4].

## 3-Fast Fourier Transform (FFT)

The Fourier Transform is an important image processing tool which is used to decompose an image into its sine and cosine components. The output of the transformation represents the image in the Fourier or frequency domain, while the input image is the spatial domain equivalent. In the Fourier domain image, each point represents a particular frequency contained in the spatial domain image [5].

The Fourier transform has found numerous uses, including vibration analysis in mechanical engineering, circuit analysis in electrical engineering, and here in computer imaging. This transform allows for the decomposition of an image into a weighted sum of two-dimension sinusoidal terms. Assuming an NxN image, the equation for twodimension Fourier transform is [4]:

$$
\begin{equation*}
F(u, v)=\frac{1}{N} \sum_{r=0}^{N-1} \sum_{c=0}^{N-1} I(r, c) e^{-j 2 \pi \frac{(u r+u c)}{N}} \tag{1}
\end{equation*}
$$

The base of the natural logarithmic function e is about 2.71828; j the imaginary coordinate for complex number, equals $\sqrt{-1}$ the basis functions are sinusoidal in nature, as can be seen by Euler's identity [4]:

$$
\begin{equation*}
e^{j x}=\cos x+j \sin x \tag{2}
\end{equation*}
$$

So we can also write the Fourier transform equation as:
$F(u, v)=\frac{1}{N} \sum_{r=0}^{N-1} \sum_{c=0}^{N-1} I(r, c)\left[\cos \left(\frac{2 \pi}{N}(u r+v c)\right)+j \sin \left(\frac{2 \pi}{N}(u r+v c)\right)\right]$
( $u, v$ ) is also complex, with the real part corresponding to the cosine terms and the imaginary part corresponding to the sine terms. So a complex spectral component is represented by:

$$
\begin{equation*}
F(u, v)=R(u, v)+j I(u, v) \tag{4}
\end{equation*}
$$

Where $\mathrm{R}(\mathrm{u}, \mathrm{v})$ is the real part and $\mathrm{I}(\mathrm{u}, \mathrm{v})$ is the imaginary part, then we can define the magnitude and phase of a complex spectral component as [4]:

$$
\begin{gather*}
\text { MAGNITUDE }={\sqrt{[R(u, v)]^{2}+[I(u, v)]^{2}}}^{2}=|F(u, v)|  \tag{5}\\
\text { PHASE }=\Phi(u, v)=\tan ^{-1\left[\frac{I(u, v)}{R(u, v)}\right]}
\end{gather*}
$$

After perform the transform, to get our original image back, the inverse transform is applied. So, the inverse Fourier transform is given by [4]:

$$
\begin{equation*}
F^{-1}[F(u, v)]=I(r, c)=\frac{1}{N} \sum_{u=0}^{N-1} \sum_{v=0}^{N-1} F(u, v)^{j 2 \pi \frac{(u r+v c)}{N}} \tag{7}
\end{equation*}
$$

The $\mathrm{F}^{-1}$ [ ] Notation represents the inverse transform. This equation illustrates that the function $\mathrm{I}(\mathrm{r}, \mathrm{c})$ is represented by a weight sum of the basis functions and that the transform coefficients $\mathrm{F}(\mathrm{u}, \mathrm{v})$ are weights. With the inverse Fourier transform, the sign on the basis functions exponent is changed from -1 to +1 . However, this corresponds only to the phase and not the frequency and magnitude of the basis functions [5].

## 4- Calculate mean value and variance

The mean is a measure of average gray level in an image and the variance (standard deviation), which is a measure of average contrast [6]. So instead of using the image histogram directly for enhancement. We can use instead some statistical parameters obtainable directly from the histogram. Let $r$ denote a discrete random variable representing discrete gray-levels in the range [0, L-1], and let p(ri) denote the normalized histogram component corresponding to the $i$ th value of $\mathrm{r} . \mathrm{P}$ (ri) as an estimate of the probability of occurrence of gray level ri. The nth moment of r about its mean is defined as [6]:

$$
\begin{equation*}
\mu_{\mathrm{n}}(\mathrm{r})=\sum_{i=0}^{L-1}\left(r_{i}-m\right)^{n} p\left(r_{i}\right) \tag{8}
\end{equation*}
$$

Where m is the mean value of r (its average gray level):

$$
\begin{equation*}
\mathrm{m}=\sum_{i=0}^{L-1} r i p\left(r_{i}\right) \tag{9}
\end{equation*}
$$

It follows from Equation (8) and (9) that $\mu_{0}=1$ and $\mu_{1}=0$. The second moment is given by [6]:

$$
\begin{equation*}
\mu_{2}(\mathrm{r})=\sum_{i=0}^{L-1}\left(r_{i}-m\right)^{n} p\left(r_{i}\right) \tag{10}
\end{equation*}
$$

This expression is considered as the variance of r , which is denoted conventially by $\sigma(r)$. The standard deviation is defined simply as the square root of the variance [6].

The global mean and variance are measured over an entire image and are useful primarily for gross adjustments of overall intensity and contrast. A much more powerful use of these two measures is in local enhancement, where the local mean and variance are used as the basis for making changes that depend on characteristics in a predefined region about each pixel in the image [7].

Let ( $x, y$ ) be the coordinates of a pixel in an image, and let Sxy denote a neighbourhood (subimage) of specified size, centered at (x,y). From Eq.(9) the mean value $\mathrm{m}_{\mathrm{sxy}}$ of the pixels in Sxy can be compared using the expression

$$
\begin{equation*}
\mathrm{m}_{\mathrm{sxy}}=\sum_{(s, t) \in S x y} r_{\mathrm{s}, t} p\left(r_{s, t}\right) \tag{11}
\end{equation*}
$$

Where rs,t is the gray level at coordinates ( $s, t$ ) in the neighbourhood, and $p(r s, t)$ is the neighbourhood normalized histogram component corresponding to that value of gray level. Similarly, from Eq.(10), the gray-level variance of the pixels in region Sxy is given by:

$$
\begin{equation*}
\sigma_{S x y}^{2}=\sum_{(s, t) \in S x y}\left[r_{s, t}-\mathrm{msxy}\right]^{2} p\left(r_{s, t}\right) \tag{12}
\end{equation*}
$$

The local mean is a measure of average gray level in neighbourhood Sxy, and the variance (or standard deviation) is a measure of contrast in that neighbourhood [6]. An important aspect of image processing using the local mean and variance is the flexibility they afford in developing simple, yet powerful enhancement techniques based on statistical measures that have a close, predicable correspondence with image appearance [8].

6-System Model (the block diagram)

Figure (1): Block diagram for evaluate discriminator power (Dp).

## 7- The algorithm

Step 1: Read two-dimensions bit map images (256) colors and put these images in two dimensions array. Each value in the matrix represent pixel in the image.
Step 2: read 8 bit Gray scale image.
Step 3: Implement the set matrix, Aij, by choosing the Fast Fourier (FFT) coefficients of the position i and j for all classes and all images:

$$
\text { Aij }=\left[\begin{array}{cccc}
x_{i j(1,1)} & x i j(1,2) & \ldots . & x i j(1, c) \\
x i j(2,1) & x i j(2,2) & \ldots . & x i j(2, c) \\
\cdot & \cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot & \cdot \\
x i j(s, 1) & x i j(s, 2) & \ldots . & x i j(s, c)
\end{array}\right]_{S X C}
$$

Step 4: Calculate the mean value of each class according to the following:-

$$
\begin{equation*}
\mathrm{Mi}^{\mathrm{c}} \mathrm{j}=\frac{1}{S} \sum_{s=1}^{S} A i j(s, c), \quad \mathrm{c}=1,2, \ldots, \mathrm{C} \tag{13}
\end{equation*}
$$

$\mathrm{Mi}^{\mathrm{C}} \mathrm{j}$ : is the mean value of each class.
Step 5: Calculate variance of each class:

$$
\begin{equation*}
\mathrm{Vi}^{\mathrm{c}} \mathrm{j}=\sum_{S=1}^{s}\left(A_{i j}(s, c)-M i^{c} j\right)^{2}, \quad \mathrm{c}=1,2, \ldots, \mathrm{C} \tag{14}
\end{equation*}
$$

$\mathrm{Vi}^{\mathrm{c}} \mathrm{j}$ : is the variance of each class.
Step 6: Average the variance of all the classes:

$$
\begin{equation*}
\mathrm{Vi}^{\mathrm{w}} \mathrm{j}=\frac{1}{C} \sum_{c=1}^{C} V i^{c} j \tag{15}
\end{equation*}
$$

$\mathrm{Vi}^{\mathrm{w}} \mathrm{j}$ : is the average variance of all class.
Step 7: Calculate the mean of all samples:

$$
\begin{equation*}
\mathrm{Mij}=\frac{1}{s \times c} \sum_{c=1}^{c} \sum_{s=1}^{s} A_{i j}(s, c) \tag{16}
\end{equation*}
$$

Mij: is the mean of all sample images.
$\mathrm{s} \times \mathrm{c}$ : is the image dimension (width X height)
Step 8: Calculate the variance of all the samples:

$$
\begin{equation*}
V i^{B} j=\sum_{c=1}^{C} \sum_{s=1}^{S}\left(A_{i j}(s, c)-M i j\right)^{2} \tag{17}
\end{equation*}
$$

$\mathrm{Vi}^{\mathrm{B}} \mathrm{j}$ : is the variance of all sample images.

Step 9: From Eq.(5) and (7) ,we can estimate the discriminator power for location (i,j) according to the following equation:
$\mathrm{D}(\mathrm{i}, \mathrm{j})=\frac{V_{i^{B}{ }_{j}}}{V_{i^{W} j}} \quad 1 \leq \mathrm{i} \leq \mathrm{m}, \quad 1 \leq \mathrm{j} \leq \mathrm{n}$
$\mathrm{Vi}^{\mathrm{B}} \mathrm{j}$ : is the variance of all sample images.
$\mathrm{Vi}^{\mathrm{W}} \mathrm{j}$ : is the average variance of all class.
$(\mathrm{m}, \mathrm{n}):$ is the image dimensions.
Step 10: Transform two dimensions matrix into one dimension matrix.
So, to transform two dimensions matrix into one dimension, we should apply the following equation:-

Location (Z) $=\mathrm{Y} \times$ width +X
Since, location (Z): mean the location in one dimension array.
X : mean the X -axis.
Y : mean the Y -axis.
Z: mean location in one dimension matrix.
Example: Transform two dimensions matrix to one dimension
X-axis
Y-axis $\left.\begin{array}{|c|c|c|c|c|}\hline & 1 & 2 & 3 & 3 \\ \hline \begin{array}{cc}(1,1) \\ 1\end{array} & (1,2) & (1,3) & (1,4) \\ 2\end{array}\right)$

Figure (2): show the two dimensions matrix.

From the previous matrix, location (7) is calculated as follows:
Location $(Z)=(Y-1) \times$ width $+X$
Location (7) $=(2-1) \times 4+3$

$$
\begin{aligned}
& =1 \times 4+3 \\
& =4+3=7
\end{aligned}
$$

Location (10) is calculated as follows:
Location $(\mathrm{Z})=(\mathrm{Y}-1) \times$ width +X
Location (10) $=(3-1) \times 4+2$

$$
=2 \times 4+2
$$

$$
=8+2=10 \quad \text { and so on. }
$$

## 8 - Experimental Results

In this paper, all computers programming works were done by using $\mathrm{C}++$ language under window. The discriminator power ( Dp ) of several image tested will be taken as shown in figure (3), (4) and figure (5) apply the previously described methods as in the followings tests:-

For the following figure, the discriminator power ( Dp ) will shown in table (1)

Figure (3): face (1).
For the following figure, the discriminator power will shown in table (2)

Figure (4): face (2).
For the following figure, the discriminator power will shown in table (3)

Figure (5): face (3).

The discriminator power ( Dp ) of figure (3) is shown below:

| location <br> x | Location y | Discriminator power (Dp) | Location <br> x | Location y | Discriminator power (Dp) |

## 9- Conclusions

A summary of some important conclusions is presented as below:
1- Take the most effective attributes in the image (maximum 50 values), store these values in database and compare these values with other attributes. This will reduce storage space, quick the search time, decrease computational cost.

2- The purpose of several tested images to determine the locations of each attributes in the image to take the final results, hence each image take the same locations.

3- In this paper, decrease or increase the attributes in the image according to the nature of person's information. So, we can deduce or combine other statistical rules in mathematical computations.

4- Using (FFT) as an excellent tool for face pattern recognition using personal computer. FFT function could be easily applied with less time consuming, and is quite simple in application. So, the parameters obtained for face recognition directly fit to the FFT function.
